Doppler Sonar: Utilizes ultrasound waves emitted into the water. The frequency shift of the returning echoes correlates to water velocity relative to the vessel, providing high-precision readings in various conditions, including high currents or low speeds.

Impeller-based Sensors: Mechanical impellers spin as water flows past them, generating electrical signals proportional to water speed. While cost-effective, they are susceptible to fouling and damage in certain environments.

Electromagnetic Sensors: Use electromagnetic induction principles; water flowing through a magnetic field generates a voltage proportional to flow speed. These sensors are less prone to biofouling and debris interference.

GPS SOG: Although not a sensor per se, GPS data serves as an essential reference point, especially when water conditions cause other sensors to falter.

2.2 Sensor Fusion Algorithms

The heart of the Naviknot system lies in its ability to synthesize data from multiple sensors. The onboard processor:

- Compares readings from all sensors.
- Applies weighting algorithms to prioritize the most reliable signals.
- Detects anomalies or discrepancies.
- Outputs a unified, highly accurate speed measurement.

This fusion process enhances reliability, ensures consistency, and reduces the likelihood of incorrect readings that could impact navigation or safety.
