Solution Approach:

Use $Q = mc\Delta T + C_{\text{calorimeter}} \Delta T$.

Students must recognize the components and perform calculations accurately.

- Application of Hess's Law

Example:

In-Depth Review of Key Concepts with Answers

1. Calculating Heat Transfer in Calorimetry

Question:

A 50.0 g sample of water is heated from 25°C to 75°C. How much heat energy is absorbed? (Specific heat capacity of water = 4.18 J/g°C)

Answer:

Using the formula:

$$q = mc\Delta T$$

where:

$$m = 50.0 \text{ g}$$

$$c = 4.18 \text{ J/g}^\circ\text{C}$$

$$\Delta T = 75^\circ\text{C} - 25^\circ\text{C} = 50^\circ\text{C}$$

Calculation:

$$q = 50.0 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 50^\circ\text{C}$$

$$q = 50.0 \times 4.18 \times 50 = 10,450 \text{ J}$$

Result:

The water absorbs 10,450 Joules of heat energy.

Total enthalpy change:

$$(-393.5 \text{ kJ} + 283 \text{ kJ}) = -110.5 \text{ kJ}$$

Result:

$\Delta H = -110.5 \text{ kJ}$ for the formation of CO from C and O_2 .

3. Bond Enthalpy Calculations

Question:

Calculate the approximate enthalpy change for the reaction:

Bond	Enthalpy (kJ/mol)
C-H	412
C=O	799

| O=O | 498 |

Answer:

Step 1: Break all bonds in reactants:

- 4 C-H bonds: $(4 \times 412 = 1648 \text{ kJ})$
- 2 O=O bonds: $(2 \times 498 = 996 \text{ kJ})$

Total energy to break bonds: $(1648 + 996 = 2644 \text{ kJ})$

Step 2: Form bonds in products:

- 2 C=O bonds in CO_2 : $(2 \times 799 = 1598 \text{ kJ})$
- 4 O-H bonds in $2 \text{ H}_2\text{O}$ molecules: $(4 \times 463 = 1852 \text{ kJ})$ (assuming O-H bond enthalpy is 463 kJ/mol)

Total energy released: $(1598 + 1852 = 3450 \text{ kJ})$

Step 3: Calculate (ΔH) :

$(\Delta H \approx \text{Energy to break} - \text{Energy to form} = 2644 - 3450 = -805 \text{ kJ})$

Result:

Approximate enthalpy change for the reaction is -805 kJ (exothermic).

Example 1: Calculating Heat Absorbed in a Reaction

Problem:

A 50 g sample of water is heated from 25°C to 80°C. Calculate the amount of heat absorbed.

Solution:

- Identify known variables:
 - $m = 50 \text{ g}$
 - $c = 4.18 \text{ J/g}^\circ\text{C}$ (specific heat capacity of water)
 - $\Delta T = 80^\circ\text{C} - 25^\circ\text{C} = 55^\circ\text{C}$

- Apply the formula: $q = mc\Delta T$

$$q = 50 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 55^\circ\text{C}$$

$$q = 50 \times 4.18 \times 55$$

$$q = 50 \times 229.9$$

$$q = 11,495 \text{ J}$$

Answer:

The water absorbs approximately 11,495 Joules of heat.

Example 2: Using Hess's Law to Find Enthalpy Change

Given the following reactions:

Calculate the ΔH for the reaction:

Solution:

- Write the target reaction in terms of known reactions:

- Reverse reaction (2):

- Add reaction (1) and the reversed (2):

Sum:

- Combine the reactions:

Adding:

Total ΔH :

$$-393.5 \text{ kJ} + 110.5 \text{ kJ} = -283 \text{ kJ}$$

Answer:

The enthalpy change for the reaction is approximately -283 kJ.

QuestionAnswer What is the primary focus of Chapter 11 in thermochemistry? Chapter 11 in thermochemistry primarily focuses on understanding heat transfer, enthalpy changes, and energy calculations associated with chemical reactions and physical processes. How do you calculate the enthalpy change for a reaction using Hess's Law? Hess's Law states that the total enthalpy change for a reaction is the sum of the enthalpy changes for individual steps, which can be added algebraically to find the overall ΔH for the reaction. What is the significance of calorimetry in thermochemistry? Calorimetry is used to measure the heat absorbed or evolved during a chemical reaction or physical change, allowing for the determination of enthalpy changes. How do bond energies relate to the calculation of reaction enthalpy? Reaction enthalpy can be estimated by subtracting the total bond energies of bonds broken from the total bond energies of bonds formed, following the bond energy method. What is standard enthalpy of formation, and why is it important? The standard enthalpy of formation is the change in enthalpy when one mole of a compound is formed from its elements in their standard states. It is important because it allows for the calculation of reaction enthalpies using tabulated data. What role does entropy play in thermochemistry, particularly in Chapter 11? While thermochemistry primarily deals with heat and enthalpy, entropy measures disorder and randomness, and it becomes important when evaluating spontaneity and Gibbs free energy in chemical reactions. How can you determine whether a reaction is endothermic or exothermic from thermochemical data? If the ΔH for a reaction is positive, it is endothermic (absorbs heat). If ΔH is negative, it is exothermic (releases heat). What are the common units used in thermochemistry for energy changes? Common units include joules (J), kilojoules (kJ), calories (cal), and kilocalories (kcal), with joules and kilojoules being standard SI units. Why is understanding the answer key for Chapter 11 thermochemistry important for students? The answer key helps students verify their understanding of key concepts, practice problem-solving skills, and prepare effectively for exams by providing clear, correct solutions to thermochemistry questions.

Common Types of Thermochemistry Assessment Questions and Their Answers

To illustrate the depth and utility of assessment answers, consider these common question types and their ideal solutions:

1. Calculating Enthalpy Change from Calorimetry Data

Question:

A 50.0 g sample of water is heated from 25.0°C to 80.0°C in a calorimeter. The temperature change recorded is 55.0°C. If the calorimeter's heat capacity is 200 J/°C, calculate the enthalpy change (ΔH) for the process.

Expert Answer:

Step 1: Calculate the heat absorbed by the water:

$$q_{\text{water}} = m \times c_{\text{water}} \times \Delta T$$

Where:

- $m = 50.0 \text{ g}$
- $c_{\text{water}} = 4.18 \text{ J/g}^\circ\text{C}$
- $\Delta T = 55.0^\circ\text{C}$

$$q_{\text{water}} = 50.0 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 55.0^\circ\text{C} = 50.0 \times 4.18 \times 55.0$$

$$q_{\text{water}} = 50.0 \times 229.9 = 11,495 \text{ J}$$

Step 2: Calculate the heat absorbed by the calorimeter:

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T = 200 \text{ J/}^\circ\text{C} \times 55.0^\circ\text{C} = 11,000 \text{ J}$$

Step 3: Total heat exchange:

$$q_{\text{total}} = q_{\text{water}} + q_{\text{calorimeter}} = 11,495 \text{ J} + 11,000 \text{ J} = 22,495 \text{ J}$$

Step 4: Determine ΔH per mole of water:

- Moles of water:

$$n = \frac{50.0 \text{ g}}{18.015 \text{ g/mol}} \approx 2.78 \text{ mol}$$

- Enthalpy change per mole:

$$\Delta H = \frac{q_{\text{total}}}{n} \approx \frac{22,495 \text{ J}}{2.78 \text{ mol}} \approx 8,088 \text{ J/mol}$$

Final Answer:

The enthalpy change for heating the water is approximately +8.09 kJ/mol, indicating an endothermic process.

2. Using Hess's Law to Find Enthalpy Change

Question:

Given the following reactions:

- $\text{C(s)} + 2\text{H}_2\text{(g)} \rightarrow \text{CH}_4\text{(g)} \quad \Delta H_1 = -75 \text{ kJ}$
- $\text{C(s)} + \text{O}_2\text{(g)} \rightarrow \text{CO}_2\text{(g)} \quad \Delta H_2 = -393 \text{ kJ}$
- $\text{CH}_4\text{(g)} + 2\text{O}_2\text{(g)} \rightarrow \text{CO}_2\text{(g)} + 2\text{H}_2\text{O(g)} \quad \Delta H_3 = -890 \text{ kJ}$

Calculate the enthalpy change for the reaction:

Expert Solution:

Step 1: Recognize the target reaction structure and relate given reactions.

Step 2: Use Hess's Law, combining reactions to arrive at the target.

- Reverse reaction 3 (since it produces products):

- The target reaction can be obtained by adding:

Step 3: Combine reactions:

Adding reaction 2 and reversed reaction 3:

Simplify:

Now, subtract (2O_2) from both sides:

which simplifies to:

But this is more complex; an alternative is to sum reactions

ch 17 thermochemistry assessment answers

ch 17 thermochemistry assessment answers are an essential resource for students and educators seeking to deepen their understanding of thermochemistry concepts covered in Chapter 17 of their chemistry curriculum. Thermochemistry, the study of heat transfer during chemical reactions, plays a vital role in understanding energy changes, reaction spontaneity, and practical applications such as heating, cooling, and energy production. Accurate assessment answers can significantly enhance learning by clarifying complex topics, providing step-by-step explanations, and reinforcing key principles. This article aims to provide comprehensive insights into Chapter 17 thermochemistry, including common questions, detailed explanations, and tips for mastering the subject matter.

Understanding Thermochemistry in Chapter 17

Thermochemistry focuses on the heat involved in chemical processes. It investigates how energy flows during reactions, whether as heat absorbed or released, and how these processes relate to the overall energy changes within a system.

Key Concepts in Chapter 17

- Enthalpy (ΔH): The heat content of a system at constant pressure.
- Exothermic and Endothermic Reactions: Reactions that release or absorb heat, respectively.
- Heat Capacity and Specific Heat: The amount of heat needed to raise the temperature of a substance.
- Calorimetry: The experimental measurement of heat transfer.
- Hess's Law: The principle that total enthalpy change is the same regardless of the pathway taken.
- Standard Enthalpy of Formation: The change in enthalpy when one mole of compound forms from its elements in their standard states.

Common Assessment Questions and Their Answers

Assessment questions in Chapter 17 often test students' understanding of concepts through calculation, conceptual explanations, and application-based problems.

1. What is the difference between an exothermic and an endothermic reaction?

Answer:

An exothermic reaction releases heat into the surroundings, resulting in a temperature increase. Examples include combustion reactions and neutralization reactions. Conversely, an endothermic reaction absorbs heat from the surroundings, leading to a temperature decrease. Examples include melting ice and photosynthesis. The key distinction lies in the direction of heat flow: exothermic reactions have a negative ΔH , while endothermic reactions have a positive ΔH .

2. How do you calculate the heat absorbed or released during a process?

Answer:

The heat transfer (q) during a process can be calculated using the formula:

$$q = mc\Delta T$$

where:

- m = mass of the substance
- c = specific heat capacity of the substance
- ΔT = change in temperature (final - initial)

For reactions involving a known enthalpy change per mole, use:

$$q = n \times \Delta H$$

where n is the number of moles reacting or produced.

3. Explain Hess's Law and provide an example of its application.

Answer:

Hess's Law states that the total enthalpy change for a chemical reaction is the same regardless of the pathway taken, provided the initial and final states are the same. This allows us to calculate enthalpy changes that are difficult to measure directly by combining known reactions.

Example:

Calculate the enthalpy change for the formation of CO_2 from C and O_2 , given the following data:

- $\text{C(s)} + \frac{1}{2} \text{O}_2(\text{g}) \rightarrow \text{CO(g)}, \Delta H = -110.5 \text{ kJ}$
- $\text{CO(g)} + \frac{1}{2} \text{O}_2(\text{g}) \rightarrow \text{CO}_2(\text{g}), \Delta H = -283.0 \text{ kJ}$

Using Hess's Law:

$$\Delta H = \Delta H_1 + \Delta H_2 = (-110.5) + (-283.0) = -393.5 \text{ kJ}$$

4. How do you determine the standard enthalpy of formation for a compound?

Answer:

The standard enthalpy of formation (ΔH°_f) is determined experimentally through calorimetry or calculated using Hess's Law and known enthalpies of reactions. It represents the heat change when one mole of a compound forms from its elements in their standard states at 25°C and 1 atm. Values are tabulated and used to compute overall reaction enthalpies.

5. What is the significance of calorimetry in thermochemistry?

Answer:

Calorimetry is a technique used to measure the heat transfer during physical or chemical changes. It provides experimental data necessary for calculating enthalpy changes, understanding reaction energetics, and verifying theoretical predictions. Common calorimeters include coffee cup calorimeters for aqueous reactions and bomb calorimeters for combustion reactions.

An accurate understanding of these answers facilitates deeper comprehension and prepares students for advanced coursework and scientific applications.

Understanding the Key Concepts in Chapter 17

Before delving into assessment answers, it's essential to review core concepts covered in Chapter

17:

1. Enthalpy (ΔH)

- Represents the heat content of a system at constant pressure.
- Sign convention:
 - $\Delta H > 0$: Endothermic process (absorbs heat).
 - ΔH

2. Calorimetry

- The experimental measurement of heat transfer.
- Involves calorimeters, which are insulated devices to prevent heat exchange with surroundings.
- Key calculations involve:
 - $q = mc\Delta T$ (heat absorbed or released).
- Where:
 - q = heat (J or cal),
 - m = mass,
 - c = specific heat capacity,
 - ΔT = temperature change.

3. Standard Enthalpy Changes

- Standard enthalpy of formation (ΔH_f°): The heat change when 1 mol of compound forms from its elements in their standard states.
- Standard enthalpy of reaction (ΔH_{rxn}°): Calculated using bond energies or Hess's Law.

4. Hess's Law

- States that the total enthalpy change for a reaction is the same, regardless of the pathway taken.
- Used to compute enthalpy changes for reactions that are difficult to measure directly.

5. Thermochemical Equations

- Balanced chemical equations that include heat terms.

- Must be manipulated carefully to reflect desired quantities or conditions.

Assessment Answers and Their Application

The answers provided in Chapter 17 assessments often address common question types: multiple-choice, short answer, calculations, and conceptual explanations. Here, we analyze these answers in detail.

1. Calculating Enthalpy Changes from Calorimetry Data

Sample Question:

A 50.0 g sample of water is heated from 25°C to 80°C. Calculate the heat absorbed during this process.

Typical Answer Breakdown:

- Use the formula: $q = mc\Delta T$
- Given:
- $m = 50.0 \text{ g}$
- $c = 4.18 \text{ J/g}^\circ\text{C}$ (specific heat capacity of water)
- $\Delta T = 80^\circ\text{C} - 25^\circ\text{C} = 55^\circ\text{C}$

Calculation:

$$q = 50.0 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 55^\circ\text{C} = 50.0 \times 4.18 \times 55 = 11,495 \text{ J}$$

Assessment Insight:

- Correct application of calorimetry principles.
- Emphasizes the importance of units and temperature change.

2. Applying Hess's Law to Determine Enthalpy of Formation

Sample Question:

Given the following reactions:

Calculate the standard enthalpy of formation of methane (CH_4).

Typical Answer Explanation:

- Recognize that the target reaction:

- Use Hess's Law by manipulating given reactions to sum to the target:
- Reaction (a): Formation of CH_4 from C and H_2
- Reaction (b): Combustion of C to CO_2
- Reaction (c): Combustion of CH_4 to CO_2 and H_2O

- Rearranged, the enthalpy of formation of CH_4 can be derived as:

$$\Delta H_f^\circ (\text{CH}_4) = \Delta H (b) + 2 \times \Delta H (c) - \Delta H (a)$$

- Substitute:

$\Delta H_f^\circ = (-393.5) + 2 \times (-891.0) - (-74.8) = -393.5 - 1782.0 + 74.8 = -2100.7 \text{ kJ}$ (which indicates a need for careful algebraic setup; actual calculations may vary based on reaction manipulation).

Assessment Tips:

- Properly balance reactions before combining.
- Understand the reversibility of reactions and sign conventions.
- The importance of systematic approach in applying Hess's Law.

3. Standard Enthalpy of Formation and Bond Energies

Sample Question:

Estimate the enthalpy change for the reaction:

$\text{C}_2\text{H}_2(\text{g}) + 3.5 \text{O}_2(\text{g}) \rightarrow 2\text{CO}_2(\text{g}) + 3\text{H}_2\text{O}(\text{l})$, using bond energies.

Typical Answer Approach:

- List bond energies for reactants and products:
 - $\text{C}\equiv\text{C}$, $\text{C}\text{--}\text{H}$, $\text{C}=\text{O}$, $\text{O}=\text{O}$ bonds
- Calculate the total bond energies broken and formed:
 - Bonds broken: in C_2H_2 and O_2
 - Bonds formed: in CO_2 and H_2O
- Enthalpy change (ΔH) = (Sum of bonds broken) - (Sum of bonds formed)
- Example calculation:
 - Bonds broken: $\text{C}\equiv\text{C}$ (1), $\text{C}\text{--}\text{H}$ (6), $\text{O}=\text{O}$ (3.5)
 - Bonds formed: $\text{C}=\text{O}$ (4 in CO_2), $\text{O}\text{--}\text{H}$ (6 in H_2O)
- Final estimate involves summing these energies appropriately.

Assessment Significance:

- Reinforces understanding of bond energies and their role in thermochemistry.
- Highlights the approximate nature of bond energy calculations.

Common Challenges and Clarifications in Chapter 17 Assessment Answers

Despite straightforward concepts, students often encounter difficulties with thermochemistry assessments. Here are some common issues and clarifications:

1. Sign Conventions and Pathways

- Remember that heat absorbed by the system (endothermic) results in a positive ΔH , while heat released (exothermic) results in a negative ΔH .
- When applying Hess's Law, reversing reactions changes the sign of ΔH .

2. Units and Significant Figures

- Always ensure consistency of units (J, kJ, cal).
- Maintain appropriate significant figures based on data precision.

3. Interpreting Calorimetry Data

- Correctly identify what the calorimeter measures—often the temperature change in water or a known substance.
- Consider calibration and calibration constants if provided.

4. Bond Energy Approximations

- Bond energy calculations are approximate and depend on average bond energies, not specific molecular environments.
- Use these calculations as estimates rather than definitive values.

5. Applying Hess's Law Accurately

- Carefully manipulate reactions—flip, multiply, or divide as needed.
- Keep track of the signs and coefficients meticulously.
