Sample Questions and Answers for Modern Biology Test B

Practicing with sample questions is an effective way to prepare for Test B. Below are representative questions along with detailed answers to enhance understanding.

Question 1: Multiple Choice

Which organelle is primarily responsible for energy production in a cell?

- A) Nucleus
- B) Mitochondria
- C) Ribosome
- D) Endoplasmic reticulum

Answer: B) Mitochondria

Explanation: Mitochondria are known as the "powerhouses" of the cell because they generate ATP through cellular respiration, providing energy for various cellular activities.

Question 2: Short Answer

Describe the process of DNA replication.

Answer:

DNA replication is the process by which a cell copies its DNA before cell division. The process involves several steps:

- Unwinding: The enzyme helicase unwinds the double helix, separating the strands.
- Priming: Primase synthesizes short RNA primers complementary to the DNA strands.
- Elongation: DNA polymerase adds new nucleotides to the 3' end of the primers, synthesizing the new strand in a 5' to 3' direction.
- Leading and lagging strands: The leading strand is synthesized continuously, while the lagging strand is synthesized in short fragments called Okazaki fragments.
- Ligation: DNA ligase joins the Okazaki fragments to form a continuous strand.
- Result: Two identical DNA molecules are formed, each composed of one old and one new strand (semi-conservative replication).

Question 3: Diagram-Based

Label the parts of a neuron in the diagram below.

(Imagine a diagram showing a typical neuron with parts labeled)

Answer:

- Dendrites
- Cell body (soma)
- Nucleus
- Axon
- Myelin sheath
- Axon terminals

Explanation:

Dendrites receive signals from other neurons, the cell body processes incoming signals, and the axon conducts electrical impulses away from the cell body. The myelin sheath insulates the axon, speeding up signal transmission, while axon terminals transmit signals to other neurons.

Question 4: Application-Based

Explain how natural selection can lead to the development of antibiotic resistance in bacteria.

Answer:

Natural selection occurs when there is variation within a population, and some individuals possess traits that confer survival advantages. In the case of bacteria:

- Some bacteria may naturally carry genetic mutations that make them resistant to antibiotics.
- When antibiotics are used, sensitive bacteria are killed, but resistant bacteria survive.
- These resistant bacteria reproduce, passing on their resistance genes.
- Over time, the population becomes dominated by resistant strains, making antibiotics less effective.
- This process underscores the importance of responsible antibiotic use and ongoing research to combat resistance.

Section 2: Short Answer Questions

Q3: Describe the process of photosynthesis and its significance.

Answer:

Photosynthesis is the process by which green plants, algae, and some bacteria convert light energy into chemical energy stored in glucose molecules. It occurs primarily in the chloroplasts and involves two main stages:

- Light-dependent reactions: Capture light energy to produce ATP and NADPH.
- Light-independent reactions (Calvin cycle): Use ATP and NADPH to fix carbon dioxide into glucose.

Significance: Photosynthesis is vital for converting solar energy into a usable form, supporting the food chain, and maintaining atmospheric oxygen levels.

Q4: Explain the concept of natural selection with an example.

Answer:

Natural selection is the process where organisms with advantageous traits are more likely to survive and reproduce, passing those traits to their offspring. Over generations, this leads to evolution.
