Interrupt vectors are specific memory addresses that contain the starting addresses of interrupt service routines (ISRs). When an interrupt occurs, the microcontroller jumps to the corresponding vector to execute the ISR, allowing the system to respond quickly to external or internal events. Explain the difference between polling and interrupt-driven data transfer. Polling involves the CPU actively checking the status of a device at regular intervals to see if it needs attention, which can be inefficient. Interrupt-driven transfer allows the device to notify the CPU via an interrupt when it requires service, enabling more efficient CPU utilization and responsiveness. What are the typical I/O interfaces available in microcontrollers? Microcontrollers generally provide digital I/O pins, analog input pins (ADC), communication interfaces like UART, SPI, I2C, and PWM outputs for controlling external devices such as motors, sensors, and displays. How does a watchdog timer function in a microcontroller system? A watchdog timer is a hardware timer that resets the microcontroller if the system becomes

unresponsive or enters an infinite loop. The software must periodically reset or 'kick' the watchdog to prevent a system reset, thereby enhancing system reliability.
