Eurocode Footing Design Spreadsheet: A Modern Tool for Structural Engineers

Introduction

Eurocode footing design spreadsheet has become an essential resource for structural engineers seeking to streamline the complex process of designing foundations in accordance with European standards. As construction projects grow in scale and complexity, the need for precise, efficient, and compliant foundation design tools has never been greater. This article explores the purpose, features, and practical application of these advanced spreadsheets, highlighting how they facilitate safer, faster, and more reliable footing designs aligned with Eurocode regulations.

Understanding the Eurocode Framework for Foundation Design

What Is the Eurocode?

The Eurocode is a set of European standards (EN standards) that provide a comprehensive framework for the structural design of buildings and civil engineering works. Specifically, EN 1997 (Eurocode 7) addresses geotechnical design, including foundations, slopes, and retaining structures.

Why Is Eurocode Critical for Foundation Design?

Eurocode ensures uniform safety and performance criteria across European countries. For foundation design, it introduces specific methods and partial factors to account for uncertainties in soil properties, loadings, and material strengths. Compliance with Eurocode ensures that structures are resilient, safe, and economically optimized.

The Role of Footing Design in Structural Engineering

Foundations as Structural Pillars

Foundations are the bedrock of any structure, transferring loads safely to the ground. The design process involves determining appropriate dimensions, reinforcement, and materials to prevent failure modes such as bearing capacity failure, excessive settlement, or structural instability.

DESIGN CONCRETE FOUNDATION EXAMPLES USING EUROCODE 2

design concrete foundation examples using eurocode 2 is a fundamental aspect of structural engineering that ensures safety, durability, and compliance with European standards. Eurocode 2 (EN 1992-1-1) provides comprehensive guidelines for the design of concrete structures, including foundations, to optimize performance under various loading conditions. Proper understanding and application of these standards are essential for engineers aiming to develop efficient, reliable, and code-compliant foundation solutions. In this article, we will explore detailed examples of designing concrete foundations based on Eurocode 2, covering different types of foundations, key design principles, and practical considerations.

Overview of Eurocode 2 for Concrete Foundation Design

Eurocode 2 (EN 1992-1-1) is part of the European Standard suite that governs the design of concrete structures. Its main objectives are to ensure structural safety, serviceability, and durability. When designing concrete foundations, Eurocode 2 provides rules for:

- Material properties and testing
- Structural analysis and load combinations
- Design of reinforcement
- Crack control
- Durability considerations

Understanding these aspects is crucial for developing foundation solutions that meet regulatory requirements and perform effectively throughout their lifespan.

Types of Concrete Foundations Covered by Eurocode 2

Eurocode 2 applies to various foundation types, including:

1. Strip Foundations

Used primarily for load-bearing walls, strip foundations are continuous strips of concrete that support load-bearing walls and distribute loads over a wider area.

2. Raft (Mat) Foundations

A large concrete slab supporting multiple columns or walls, suitable for poor soil conditions or heavy loads.

3. Pad Foundations

Isolated foundations supporting individual columns or piers, designed to transfer concentrated loads.

4. Pile Foundations

Deep foundations used when shallow foundations are insufficient, transferring loads through piles into stable soil layers.

Each foundation type requires specific design considerations, which we will explore through examples.

Design Principles for Concrete Foundations per Eurocode 2

Before delving into examples, it's essential to understand the core principles guiding foundation design under Eurocode 2:

- **Load Analysis:** Consider all relevant loads, including dead loads, live loads, imposed loads, and environmental factors, combined according to EN 1990 principles.
- **Soil-Structure Interaction:** Evaluate soil bearing capacity, settlement, and stability to ensure foundation adequacy.
- **Material Selection:** Use concrete and reinforcement grades compliant with Eurocode specifications, considering durability and environmental exposure.
- **Reinforcement Design:** Calculate reinforcement requirements to resist bending, shear, and axial forces, ensuring ductility and safety.
- **Serviceability and Crack Control:** Limit crack widths and deflections to acceptable levels based on serviceability criteria.
- **Durability:** Design for resistance against environmental effects, such as freeze-thaw cycles, corrosion, and chemical attack.

Concrete Foundation Design Examples Using Eurocode 2

In this section, we present detailed examples illustrating the application of Eurocode 2 standards to different foundation types. Each example includes assumptions, calculations, and design considerations.

Example 1: Designing a Strip Foundation for a Load-Bearing Wall

Project Overview:

- Building load: 150 kN/m (per meter length of wall)
- Soil bearing capacity: 100 kPa
- Width of strip foundation: To be determined
- Concrete grade: C20/25 ($f_{ck} = 20$ MPa)
- Reinforcement: B500B

Step 1: Calculate the required foundation width

Using Eurocode 2, the ultimate bearing capacity (q_u) is given by:

$$q_u = \text{soil bearing capacity} \times \text{partial safety factor}$$

Assuming a partial safety factor for soil $(\gamma_s = 1.25)$:

$$q_{allow} = \frac{100 \text{ kPa}}{1.25} = 80 \text{ kPa}$$

The foundation must distribute the load without exceeding the soil strength:

$$b = \frac{N_{ed}}{q_{allow} \times L}$$

Where:

- $N_{ed} = 150 \text{ kN/m}$
- L is the length of the foundation (assume 1 m for per meter calculation)

Rearranged:

$$b = \frac{150 \text{ kN}}{80 \text{ kPa} \times 1 \text{ m}} = \frac{150 \text{ kN}}{80 \text{ kN/m}^2} = 1.875 \text{ m}$$

However, such a large width is impractical. To optimize, incorporate safety and settlement considerations, and choose a standard width, say 0.5 m, then verify bearing capacity adequacy.

Step 2: Check bearing capacity with chosen width

Total load per meter:

$$N_{ed} = 150 \text{ kN}$$

Ultimate bearing capacity:

$$q_u = c \times N_c + \sigma_0 \times N_q + 0.5 \times \gamma_b \times B \times N_{\gamma}$$

Assuming:

- cohesion $(c = 0)$ (cohesionless soil)
- effective stress (σ_0) at foundation level
- use Eurocode 7 charts or formulas for detailed calculation

The simplified approach suggests that a 0.5 m width foundation is sufficient if soil conditions are

favorable.

Step 3: Reinforcement Design

Calculate bending moments and shear forces based on load distribution, then determine reinforcement:

- Use Eurocode 2 formulas for bending reinforcement, considering the concrete's characteristic strength.
- Check crack widths and serviceability limits.

Step 4: Durability and Detailing

- Cover concrete minimum 50 mm for durability.
- Use reinforcement detailing per EN 1992-1-1 recommendations.

Example 2: Designing a Raft Foundation for a Small Office Building

Project Overview:

- Total load: 1,200 kN
- Building dimensions: 10 m x 15 m
- Soil bearing capacity: 150 kPa
- Concrete grade: C30/37 ($f_{ck} = 30$ MPa)
- Reinforcement: B500B

Step 1: Determine Foundation Thickness

Assuming a uniform load and aiming for minimal settlement, choose a thickness (h) based on Eurocode 2 guidelines:

$$h = \frac{N_{total}}{q_{allow} \times B \times L}$$

Calculate:

$$q_{allow} = \frac{150 \text{ kPa}}{1.35} \approx 111 \text{ kPa}$$

Total area:

$$A_{\text{foundation}} = B \times L$$

Assuming a 0.5 m thick slab:

$$q_{\text{Design load per unit area}} = \frac{1,200 \text{ kN}}{10 \text{ m} \times 15 \text{ m}} = 8 \text{ kPa}$$

Check if the foundation can support this load with the chosen thickness and reinforcement.

Step 2: Reinforcement Calculation

- Bending moments and shear forces are computed for the slab.
- Design reinforcement for flexure and shear per EN 1992-1-1.

Step 3: Detailing and Durability

- Reinforcement spacing, cover, and anchorage are specified.
- Consider environmental exposure for durability.

Example 3: Designing a Pile Foundation Using Eurocode 2 Principles

Project Overview:

- Load per pile: 500 kN
- Number of piles: 4
- Soil bearing capacity at pile tip: 300 kPa
- Pile type: Concrete bored piles
- Concrete grade: C25/30

Step 1: Pile Diameter and Length

Using Eurocode 2, the pile cross-section is designed to resist axial loads and moments:

- Diameter (D) typically ranges between 0.4 m and 0.6 m.
- Length is determined by soil conditions and load transfer capacity.

Design checks include:

- Pile axial capacity:

$$N_{allow} = A_{pile} \times q_c$$

Where q_c is the characteristic soil strength at pile tip.

- Concrete and reinforcement design to resist axial and bending forces.

Step 2: Reinforcement Detailing

- Ensure reinforcement for axial load capacity and possible moments.
- Use Eurocode 2 formulas to determine reinforcement ratios and detailing.

Practical Considerations in Concrete Foundation Design Using Eurocode 2

When applying Eurocode 2 standards to real-world foundation design, engineers should also consider:

- **Site Investigation:** Accurate soil testing and analysis to determine bearing capacity, settlement potential, and soil type.

- **Load Path and Distribution:** Proper load transfer mechanisms to prevent

Design Examples Using Eurocode 2

Let's explore detailed examples illustrating the design of various foundation types.

Example 1: Isolated Concrete Pad Foundation for a Column

Project Data:

- Column load (axial): 3000 kN
- Column dimensions: 0.3 m × 0.3 m
- Soil bearing capacity (allowable): 150 kPa
- Concrete class: C25/30
- Reinforcement: Tension reinforcement as per design

Design Steps:

- Determine Foundation Size
- Ultimate bearing capacity (q_{ult}): Use simplified formulas or Terzaghi's method.
- Required bearing area (A_f):

$$A_f = \frac{N_{Ed}}{q_{allow}} = \frac{3000 \text{ kN}}{150 \text{ kPa}} = 20 \text{ m}^2$$

- Foundation dimensions: To keep the foundation square:

$$B = \sqrt{A_f} \approx 4.47 \text{ m}$$

- Design dimensions: For practicality, choose $B = 4.5 \text{ m}$.

- Check Bending and Shear

- Calculate bending moments: For a uniformly loaded foundation, approximate considering load eccentricity.

- Design reinforcement: Use Eurocode 2 formulas for tension reinforcement, ensuring minimum reinforcement ratios.

- Serviceability Checks

- Crack width: Ensure reinforcement spacing and concrete cover limit crack widths.
- Deflections: Check for overstress or excessive settlement.

- Detail Reinforcement

- Main reinforcement: Provide top and bottom bars, with anchorage lengths per Eurocode 2.
- Distribution reinforcement: To control cracking, especially near edges.

Summary: This simplified example demonstrates the initial sizing based on load and soil capacity, followed by detailed reinforcement design following Eurocode 2 directives.

Example 2: Strip Foundation Supporting a Load-Bearing Wall

Project Data:

- Wall load: 200 kN/m length
- Soil bearing capacity: 120 kPa
- Design load (factored): $1.35 \times \text{dead} + 1.5 \times \text{live}$
- Foundation width: To be determined

Design Process:

- Calculate Foundation Width

$$B = \frac{Q_{\text{factored}}}{q_{\text{allow}}}$$

Assuming the load per unit length is 200 kN/m, and the soil capacity is 120 kPa:

$$B = \frac{200 \, \text{kN/m}}{120 \, \text{kPa}} = \frac{200 \, \text{kN/m}}{120 \, \text{kN/m}^2} \approx 1.67 \, \text{m}$$

- Choose $B = 1.7 \, \text{m}$ for simplicity.

- Determine Reinforcement

- Calculate bending moments: For a uniformly distributed load, use standard formulas.
- Design reinforcement: Ensure the reinforcement area satisfies Eurocode 2 minimum requirements, typically at least 0.2% of the cross-sectional area.

- Check for Shear and Stability
- Shear capacity: Verify concrete shear capacity and provide shear reinforcement if necessary.
- Overturning and sliding: Confirm foundation's stability against lateral forces.
- Durability and Detailing
- Concrete cover: Maintain minimum cover as per Eurocode 2.
- Reinforcement detailing: Use proper anchorage, lap lengths, and spacing.

Summary: This example highlights the importance of considering load distribution, soil capacity, and reinforcement detailing in strip foundation design under Eurocode 2.

Durability and Serviceability Aspects in Foundation Design

Designing concrete foundations isn't solely about strength; durability and serviceability are equally important:

- Durability considerations:
 - Use appropriate concrete classes for environmental conditions.

- Considering construction constraints and costs

Step-by-Step Worked Example of Pile Design

This example illustrates the design process for a single pile supporting a small commercial building. The steps include site investigation, load calculation, pile capacity assessment, and final design specification.

1. Site Investigation and Soil Data

Soil profile at the site:

Soil Layer	Thickness (m)	Description	Unit Weight (kN/m³)	Young's Modulus (MPa)	Undrained Shear Strength (kPa)	
Topsoil	1.0	Loose, organic	18	10	50	
Clay Layer	3.0	Clay, stiff	20	30	150	
Firm Sand	10.0	Well-graded sand	22	50	0 (drained)	
Bedrock	N/A	Hard rock	N/A	N/A	N/A	

Design parameters:

- Building load (dead + live): 500 kN
- Service factor: 1.2 (for safety)
- Total load (factored): $500\text{ kN} \times 1.2 = 600\text{ kN}$

2. Determining the Type of Pile

Based on the soil profile, a drilled displacement pile or concrete bored pile is suitable due to the presence of stiff clay and sand layers. For this example, we select a reinforced concrete bored pile with a diameter of 0.6 m.

3. Calculating the Required Pile Capacity

A. Axial Load Components:

- Ultimate skin friction (Q_s): Resistance along the pile shaft
- End bearing capacity (Q_p): Resistance at the pile tip

B. Estimating Skin Friction (Q_s):

Using the Terzaghi's or Lambe and Whitman formula for undrained shear strength:

$$Q_s = \sum (q_{s,i} \times A_{s,i})$$

]

Where:

- ($q_{s,i}$) = average skin friction in layer i
- ($A_{s,i}$) = lateral surface area in layer i

Assumptions:

- Skin friction in clay: ($q_s = 0.5 \times s_u$)

Given ($s_u = 150$, kPa):

]

$$q_s = 0.5 \times 150 = 75, \text{kPa}$$

]

- For the sand layer, assume drained conditions and negligible skin friction for initial estimate.

Calculations:

- Pile length in clay: 3 m
- Pile length in sand: 10 m

Surface area in clay:

\[

$$A_s = \pi \times D \times L_{\text{clay}} = \pi \times 0.6 \, \text{m} \times 3 \, \text{m} \approx 5.65 \, \text{m}^2$$

\]

Skin friction in clay:

\[

$$Q_{s,\text{clay}} = q_s \times A_s = 75 \, \text{kPa} \times 5.65 \, \text{m}^2 \approx 423.75 \, \text{kN}$$

\]

Total skin friction (approximate): 424 kN

C. End Bearing Capacity (Q_p):

Assuming the pile tip is in the firm sand layer:

\[

$$Q_p = q_u \times A_p$$

\]

Where:

- (q_u) = ultimate bearing capacity of sand = $3 \times (s_u)$ (per code guidelines)

Given ($s_u = 0$) for drained sand, but for design, use a conservative estimate:

\[

$$q_{\text{u}} \approx 100 \text{ kPa}$$

$$\downarrow$$

$$\downarrow$$

$$A_{\text{p}} = \frac{\pi}{4} D^2 = \frac{\pi}{4} \times 0.6^2 \approx 0.283 \text{ m}^2$$

$$\downarrow$$

$$\downarrow$$

$$Q_{\text{p}} = 100 \text{ kPa} \times 0.283 \text{ m}^2 \approx 28.3 \text{ kN}$$

$$\downarrow$$

Given the low end bearing estimate, the pile's capacity primarily relies on skin friction in clay.

4. Determining Pile Length and Diameter

To support the factored load of 600 kN, the pile's ultimate capacity should be at least 1.5 times the load for safety:

$$\downarrow$$

$$Q_{\text{ult}} \geq 1.5 \times 600 \text{ kN} = 900 \text{ kN}$$

$$\downarrow$$

Current capacity estimate:

- Skin friction: 424 kN
- End bearing: 28.3 kN

Total capacity: approximately 452 kN, which is below the required capacity. To increase capacity, options include:

- Increasing pile length
- Increasing pile diameter

- Using a pile with better capacity in the weak layers

Adjusting pile parameters:

Suppose we increase the pile length in clay to 6 m:

$\backslash$

$$A_s = \pi \times 0.6 \times 6 \approx 11.31 \text{ m}^2$$

$\backslash$

$\backslash$

$$Q_s = 75 \text{ kPa} \times 11.31 \text{ m}^2 \approx 849.75 \text{ kN}$$

$\backslash$

Adding the end bearing:

$\backslash$

$$Q_{\text{total}} \approx 849.75 + 28.3 \approx 878 \text{ kN}$$

$\backslash$

Close to the 900 kN target, so a pile length of about 6.5 m would suffice.

Final design:

- Pile diameter: 0.6 m
- Pile length: 6.5 m
- Reinforced concrete pile with appropriate reinforcement detailing

Design Considerations and Best Practices

When designing pile foundations, consider the following:

- Soil variability: Conduct thorough geotechnical investigations.

- Load combinations: Include live, dead, wind, seismic loads.
- Pile type selection: Driven, bored, screw, or micropiles based on site conditions.
- Factor of safety (FoS): Typically between 2.0 and 3.0 for ultimate capacity.
- Settlement analysis: Ensure settlements are within acceptable limits.
- Construction constraints: Accessibility, equipment, and sequencing.
- Environmental factors: Impact on surrounding structures and ecosystems.

Conclusion

A robust pile foundation design requires a careful balance of soil properties, structural loads, and construction considerations. This worked example demonstrates the step-by-step process from site investigation to final pile specification, emphasizing the importance of accurate data, conservative estimates, and adherence to engineering standards. By following these guidelines, engineers can develop safe, efficient, and cost-effective pile foundations tailored to specific project needs.

Pile Design Foundation Worked Example: An Expert Guide to Structural Stability and Safety

In the realm of civil and structural engineering, foundations serve as the critical base upon which

entire structures are built. Among various foundation types, pile foundations are indispensable when dealing with deep, weak, or variable soil conditions. Proper design of pile foundations ensures the stability, safety, and longevity of structures ranging from high-rise buildings to bridges and industrial facilities. This article provides a comprehensive, step-by-step worked example of pile design, emphasizing the importance of each phase and the engineering principles involved.

Understanding Pile Foundations: An Overview

Before diving into the detailed worked example, it's essential to grasp the fundamental concepts of pile foundations.

What Are Pile Foundations?

Pile foundations are deep foundations that transfer structural loads through weak or compressible soils to more competent strata deep below the surface. They are typically long, slender columns made of concrete, steel, or timber, driven or drilled into the ground.

Types of Piles

- Driven Piles: Precast concrete, steel, or timber piles driven into the ground using hammers.
- Bored (Drilled) Piles: Large-diameter concrete piles cast in situ after drilling.
- Combination Piles: Use of both driven and bored techniques.

Design Considerations for Piles

- Soil properties (density, strength, type)
- Load characteristics (dead, live, dynamic)
- Structural requirements (axial load, lateral load)
- Environmental factors (water table, corrosion potential)

Step 1: Site Investigation and Soil Testing

The first step in designing a pile foundation involves acquiring accurate geotechnical data through site investigation.

Soil Sampling and Testing

- Standard Penetration Test (SPT): Provides N-values indicating soil strength.

- Laboratory Tests: Determine parameters like Cohesion (c), Friction Angle (ϕ), and Unconsolidated Shear Strength.
- Cone Penetration Test (CPT): Offers continuous profiling of soil stratification.

Typical Soil Profile (Hypothetical Data)

Layer	Depth (m)	Soil Type	Properties
1	0-3	Silty Sand	$N = 15$, $\phi = 30^\circ$, $c = 0$ kPa
2	3-8	Clay	$c = 50$ kPa, $\phi = 0^\circ$, $N = 5$
3	8-20	Dense Sand	$N = 35$, $\phi = 33^\circ$, $c = 0$ kPa
4	20+	Rock (if encountered)	Bedrock or very stiff soil

Note: The actual soil data guides the selection of pile type, length, and diameter.

Step 2: Load Estimation and Structural Analysis

Accurate load estimation is vital for designing appropriate pile capacities.

Types of Loads

- Dead Loads: The weight of the structure itself.
- Live Loads: Variable loads like occupancy or equipment.
- Environmental Loads: Wind, seismic, or water pressure.

Example Structural Load (Hypothetical Data)

Load Type	Magnitude (kN)
Dead Load (DL)	1500
Live Load (LL)	800

| Wind Load (WL) | 600 |

| Total Axial Load (P) | 2900 kN (approximate sum) |

Design must consider factors of safety and load combinations per relevant codes.

Step 3: Determining the Required Pile Capacity

The total load must be safely transferred through the pile to the soil.

Calculating Ultimate Bearing Capacity

The ultimate capacity (q_u) of a pile is derived from soil-pile interaction:

- End Bearing (Q_p): Resistance at the pile tip.
- Skin Friction (Q_s): Resistance along the pile shaft.

The total pile capacity (Q) is:

$$Q = Q_p + Q_s$$

Methodologies include:

- Static load test data
- Empirical formulas (e.g., Meyerhof, Hansen)
- Field and laboratory test results

Estimating Pile Capacity (Hypothetical Calculation)

Assuming:

- Pile diameter (D): 0.6 m
- Pile length (L): 20 m
- Soil shear parameters from tests:
 - For dense sand: $\phi = 33^\circ$, $c = 0$
 - For clay: $c = 50$ kPa, $\phi = 0^\circ$

End Bearing Capacity (q_u):

$$q_u = N_q \times \sigma'_v$$

Where:

- (N_q) = Bearing capacity factor (~ 25 for $\phi = 33^\circ$)
- (σ'_v) = Effective overburden pressure at pile tip

At 20 m depth:

$$\sigma'_v = \text{unit weight} \times \text{depth}$$

Assuming:

- (γ) (unit weight of dense sand) = 18 kN/m^3

[

$$\sigma'_v = 18 \times 20 = 360, \text{ kPa}$$

]

[

$$q_u = 25 \times 360 = 9000, \text{ kPa}$$

]

End bearing resistance:

[

$$Q_p = q_u \times A$$

]

[

$$A = \frac{\pi}{4} \times D^2 = \frac{\pi}{4} \times 0.6^2 \approx 0.283, \text{ m}^2$$

\]

\[

$$Q_p = 9000 \times 0.283 \approx 2547, \text{ kN}$$

\]

Skin friction (Q_s):

Assuming an average unit skin friction (f_s):

\[

$$f_s = 0.5 \times c + \sigma'_v \times \tan \phi$$

\]

For dense sand:

\[

$$f_s = 0.5 \times 0 + 360 \times \tan 33^\circ \approx 360 \times 0.649 \approx 233, \text{ kPa}$$

\]

Surface area of the shaft:

\[

$$A_s = \pi \times D \times L = \pi \times 0.6 \times 20 \approx 37.7, \text{ m}^2$$

\]

Skin friction capacity:

\[

$$Q_s = f_s \times A_s \approx 233 \times 37.7 \approx 8780, \text{ kN}$$

\]

Total capacity:

$$Q_{total} = Q_p + Q_s \approx 2547 + 8780 = 11327 \text{ kN}$$

Considering safety factors (say, 2.5), the permissible load per pile would be approximately:

$$Q_{perm} = \frac{Q_{total}}{2.5} \approx 4530 \text{ kN}$$

Since the applied load is approximately 2900 kN, a single pile of this capacity suffices; in practice, multiple piles are used for load sharing.

Step 4: Selecting Pile Dimensions and Type

Based on capacity calculations, the next step involves choosing the pile type, diameter, length, and material.

Pile Diameter and Length

- Diameter: 0.6 m (from capacity estimates)
- Length: 20 m (to reach competent strata)

Material Choice

- Reinforced concrete is common for its durability and strength.
- Steel piles may be used where higher capacity or specific installation conditions exist.

Design Summary

Parameter	Specification

| Diameter | 0.6 m |

| Length | 20 m |

| Material | Reinforced concrete |

| Number of Piles | 3 (for load sharing) |

| Spacing | ? 3 times the diameter (~1.8 m) |

Step 5: Detailing the Pile Reinforcement and Structural Design

Designing the reinforcement details ensures the pile withstands axial loads and lateral stresses.

Reinforcement Design Considerations

- Longitudinal bars: Provide axial strength.
- Lateral ties: Maintain shape and resist buckling.
- Minimum reinforcement ratios: As per standards (e.g., 1% of cross-sectional area).

For a 0.6 m diameter pile:

- Longitudinal bars: 4-6 bars of 25-32 mm diameter.
- Ties: 8 mm or 10 mm diameter at specified spacing (e.g., every 300 mm).

Structural Checks

- Flexural strength: Ensure reinforcement can resist bending.
- Shear capacity: Verify ties and stirrups prevent shear failure.
- Crack control: Adequate cover and reinforcement ratios.

Step 6: Construction
